

SACRED: what it is made of, in one page

For: Viren (Lovable feasibility), Adam Snyder (UAT), Saroj / Infosys (supportability) · **From:** Dan Plant, Technical Superintendent, Well Control Engineering · **Date:** 2 October 2026

SACRED is five parts. They are joined by files, not by code calling code, which is why each can be judged on its own.

#	Part	What it is	Where it runs	Who owns it	Could it move to a hosted app platform?
1	The rig-side tools (WCE Rig Reporting Tool, SSORT, Precharge Pro, the AAB and Help pages)	Single self-contained HTML files. A crew opens one on a rig laptop, fills it in over hours or days with local auto-save, and presses Post. Post sends one JSON file (0.5 to 40 MB) to an HTTP endpoint. Rigs have a live connection (Starlink); the tools are file-based by design so a half-finished report survives a dropout, a reboot or a change of shift, and so a report is one file that can be kept, re-posted or recovered.	On the rig laptop, from a file. The sacred share is only where the current revision is downloaded from.	Dan Plant (owner), with their build sessions	In principle, yes; in practice it is a rebuild, not a migration. Fourteen rigs are trained on them and they are in service. A hosted form would have to match the local auto-save and the one-file record before any crew used it. Worth considering later for two reasons: live posting, and no unmanaged data left on rig machines (ORR item 27). Not for February.
2	The intake and the notification flows	Power Automate: an HTTP trigger that writes each posted file into a SharePoint library; five flows that send the precharge, CBM to NOV, AAB, Help Centre and rig-visit emails and Teams posts from a distribution workbook, with test mode and receipts.	SEADRILL-WC-DEV environment; SharePoint site WellControl	Dan, Lee Arnold co-owner	Already hosted in the Microsoft tenancy. Nothing to migrate. If the pages moved, the links the flows send would change, which is a field edit per flow.
3	The scanner and the pages	A PowerShell script (no modules) runs every ten minutes, reads the three SharePoint libraries through OneDrive sync, and writes static HTML pages, a JSON data file and per-report digests. The dashboard, the Bulletin Board, the Help Centre and the precharge pages are those static files served by IIS from the sacred share.	Dan's PC today; the sacred server (sandbox) from the week of 19 October; UAT and production when ISIT provide them	Dan (script, pages); ISIT (server and task from the transfer)	This is the part a platform could replace. The pages are read-only views of files; a hosted app could render the same views from the same data. It would need an ingestion step to take the posted files (or the scanner's normalised export) into its own store, and an authenticated path for rig users.
4	The database	Microsoft Fabric SQL database SACRED DATA (22 tables, 6 views), loaded from the scanner's normalised export on every run. No server, no secret.	Dan's Fabric workspace; capacity on Lee's cost centre from mid-November	Dan / Lee	Already hosted in the tenancy. A platform with its own database would be a second copy of the same data outside the tenancy, with its own security review.
5	Ask SACRED AI	A Copilot Studio agent that answers questions from the per-report digests in SharePoint.	Seadrill Apps PROD; Teams app approval pending since 16 September	Dan, Lee	Already hosted. Reads SharePoint; unaffected by where the pages live.

What a migration of part 3 would and would not do

Would remove: the IIS server, the share, the scheduled task and the service account for it, the server backup, and the DNS and hosting rows on ISIT's gap list. That is the hosting burden, and it is real.

Would not remove: the posting contract (part 1 posts a file; something has to receive and index it); the notification flows (part 2 stays and needs the new page links); the data model (the scanner's export is the schema; it would feed the platform's store instead of, or as well as, Fabric); the authenticated path for rig users (needed either way; the sandbox has none); the heavy-window load (7 to 10 day periods where a rig posts many large files); the rig access problem (the rigs that cannot reach the sacred server today are blocked by corporate network provisioning, not by their Starlink link; a hosted platform has to be provisioned for the rig networks the same way); the security review (a hosted platform holding rig reports with names and photographs is a larger review than static files on an internal server, not a smaller one); or the training and the people side.

Would add: a build of the dashboard views on the platform (the current dashboard is about 5,000 lines of rendering logic for reports, CBM grades, compliance, AAB, precharge and Help, written against the data file's shape), a second data store, a dependency on a vendor platform that is new to Seadrill, and a licence line.

The honest position

SACRED's hosting footprint is already small: one static web folder and one ten-minute script. The parts ISIT find hard to support are the ones with no platform answer: the file-based rig tools, the posting contract, the flows and the people process. A migration is worth doing if ISIT would rather support a hosted app than a Windows server and a scheduled task, and if the platform is provisioned for the rig networks and passes the same security review. It is not a shortcut past the integration work, because the integration work is in parts 1, 2 and 4, which stay where they are.

The useful first step for Viren is a half-day with the data file and the normalised export, to see whether the platform can render the Reports and Rig Monitoring views from them. If it can, the migration question is real and can be planned for after February. If it cannot, it is answered.
